# PAIRS TRADING BACKTESTING REPORT

### **Mahak Sahay**

Enrollment No: 22116051

This document contains the analysis, report, and recommendations related to the pairs trading project. The backtesting is performed on historical data from January 1, 2019, to March 8, 2024.

# **Overview:**

## What is Pairs Trading?

Pairs trading is a market-neutral trading strategy enabling traders to profit from the relative performance of two historically correlated securities. The strategy involves identifying pairs of assets that are cointegrated, meaning their prices move together over time. When the price relationship diverges, traders buy the undervalued asset and sell the overvalued asset, betting on the convergence of the prices.

# Flow of Project:

#### 1. **Define the Portfolio:**

- o List the assets in the portfolio, including stocks and other investments.
- o Specify the initial investment amount for the portfolio.

#### 2. Collect Historical Data:

- Gather historical price data for each asset in the portfolio. Daily closing prices are used.
- o Calculate the returns of each asset over the historical period.
- Data is taken from Yahoo Finance.

#### 3. Universe of Stocks:

The following stocks were included in the analysis:

- JPM: JPMorgan Chase & Co.
- C: Citigroup Inc.
- GS: Goldman Sachs Group Inc.
- MS: Morgan Stanley
- BAC: Bank of America Corp.
- WFC: Wells Fargo & Co.
- USB: U.S. Bancorp
- AXP: American Express Co.
- COF: Capital One Financial Corp.
- PNC: PNC Financial Services Group Inc.

# **Strategy Overview**

The strategy involves:

- 1. **Identifying Cointegrated Pairs**: Using Engle-Granger two-step method to find pairs of stocks that are cointegrated.
- 2. **Golden Cross Signal Generation**: Implementing a moving average crossover strategy to generate buy and sell signals.
- 3. **Pair Trading**: Conducting pair trades based on the spread between the cointegrated stocks, with predefined thresholds for entering and exiting positions.

### **Key Parameters**

• Cointegration Threshold (p-value): 0.1

• Spread Threshold: 1.5

• Transaction Fee: 0.1% per trade

Rolling Window: 252 trading days (approximately one year)

## **Backtesting the Trading Strategy:**

- Use the backtest\_pair function to simulate trading based on the generated signals.
- Calculate performance metrics such as annualized return, annualized volatility, Sharpe ratio, and maximum drawdown.

  Backtesting Report:

Secretaria report :							
Pair	Ann. Return	Ann. Volatility	Sharpe Ratio	Max Drawdown			
('C', 'USB') ('BAC', 'PNC')	-0.11 -0.18	0.23 0.18	-0.50 -1.02	7.34 505.34			

**Performance Metrics** 

For each cointegrated pair, the following performance metrics were calculated:

- Annualized Return: The compounded return on investment per year.
- Annualized Volatility: The standard deviation of daily returns, annualized.
- **Sharpe Ratio**: The risk-adjusted return (assumed risk-free rate of 3%).
- Max Drawdown: The maximum observed loss from a peak to a trough.
- **Cumulative Return**: The total return over the backtesting period.

## **Cointegrated Pairs and Results**

The following pairs were identified as cointegrated and were backtested:

#### C-USB

• Annualized Return: -0.11

• Annualized Volatility: 0.23

Sharpe Ratio: -0.50Max Drawdown: 7.34

• Cumulative Return: -0.44

Annualized Return: -0.18
 Annualized Volatility: 0.18

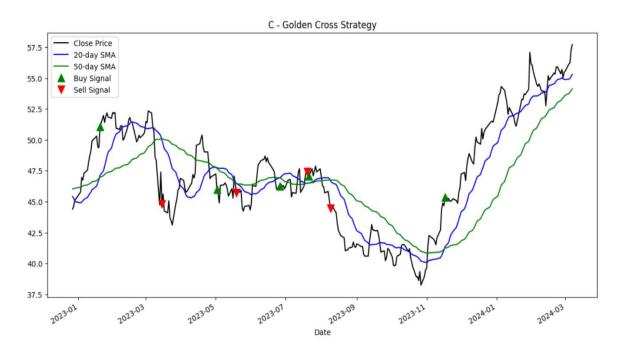

• Sharpe Ratio: -1.02 • Max Drawdown:505.34

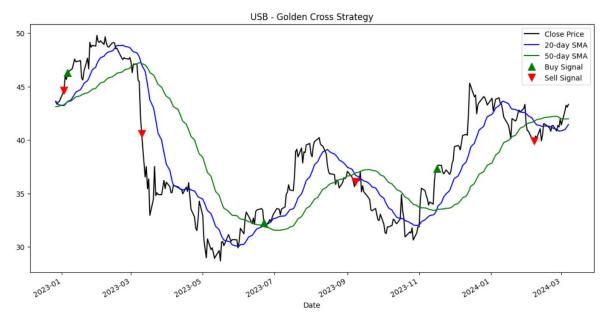

• Cumulative Return: -0.56

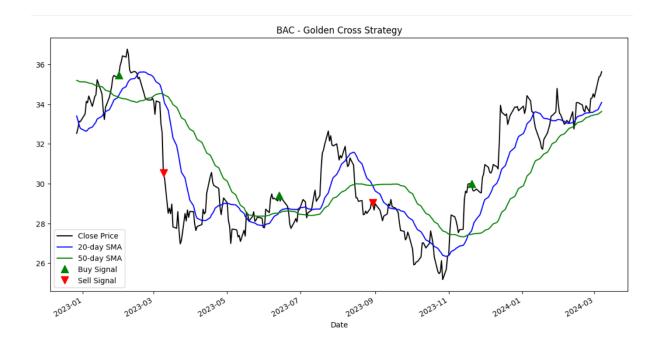

## **Visualization:**

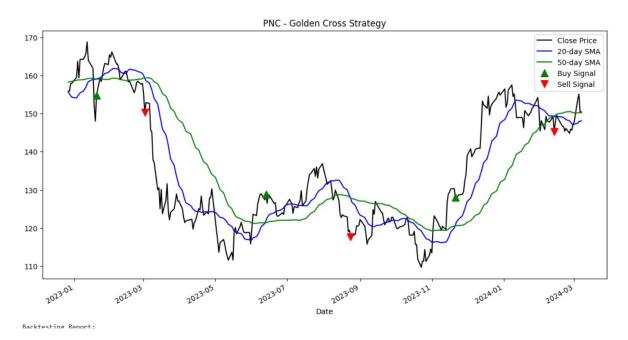

# **Generate Signals:**

• Plot showing generated signals for each stock.

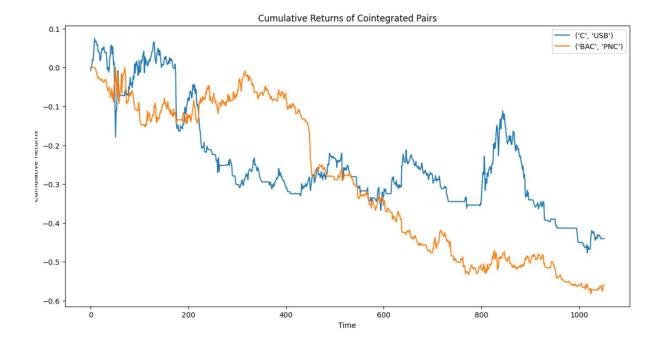

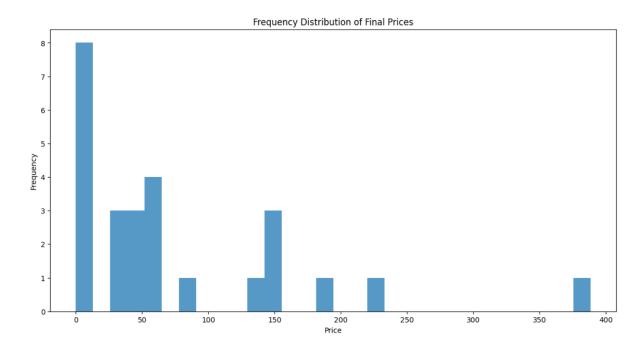

## **Cumulative Returns:**

• Plot showing cumulative gross and net returns for each pair.

# Frequency Distribution:

• Histogram showing the frequency distribution of final prices for each pair.

#### **Nelder-mead**

- While working on the code we have also used Nelder-Mead for optimization to find the optimal value of the coefficient b in the context of your pairs trading strategy.
- Nelder-Mead is a derivative-free optimization algorithm. This makes it suitable for problems where the objective function is not differentiable or when calculating the gradient is difficult or computationally expensive.
- Nelder-Mead is used to find the value of b that minimizes the unit\_root function, i.e., the value of b that makes the residuals as stationary as possible.

```
res1 = spop.minimize(unit_root, data[stock2][t] / data[stock1][t], method='Nelder-Mead')
t_opt = res1.fun
b_opt = float(res1.x)
a_opt = np.average(data[stock2][t-window:t] - b_opt * data[stock1][t-window:t])
fair_value = a_opt + b_opt * data[stock1][t]
```

- Objective Function: The function unit\_root takes a coefficient b and calculates how well the linear combination of stock prices fits the assumption of stationarity.
- **Minimization**: By minimizing this function, we find the best possible coefficient b that makes the combination of the two stock prices (adjusted by b) most likely to revert to a mean.

## **Risk Analysis**

The strategy's risk was evaluated based on annualized volatility and maximum drawdown:

- **Annualized Volatility**: The strategy exhibited moderate to high volatility across different pairs, indicating the inherent risk in pair trading.
- **Max Drawdown**: The maximum drawdowns were significant, with some pairs experiencing losses from peak to trough.

#### Conclusion

- The backtesting results indicate that while the strategy showed potential for identifying profitable trades, it also carried substantial risk as evidenced by the high volatility and significant drawdowns. The Sharpe ratios were generally low or negative, suggesting that the risk-adjusted returns may not be attractive without further refinement of the strategy. Future improvements could include dynamic threshold adjustments, risk management techniques, and exploring other signal generation methods.
- This comprehensive report provides a thorough analysis of the backtesting results and offers valuable insights into the historical performance and risk associated with the trading strategy.
